Website testing and API validation | 19 October 2026

Project scope

Two practical QA exercises covering customer journeys and API responses. SauceDemo was used to check login, product sorting, cart actions and checkout. A separate DummyJSON collection covers product data and negative API responses.

Results

Exercise	Recorded outcome
Website functionality	10 scenarios: seven baseline checks passed; three seeded defects reproduced.
API validation	10 HTTPS requests and 55 automated assertions passed.
Defect analysis	Three reports with repeat attempts, screenshots and comparisons with standard_user.

Priority findings

Checkout - High / P1: Last Name entry updates First Name and leaves a required field empty, preventing progression to order review.

Cart - High / P2: The Bolt T-Shirt is not added for problem_user. The same product is added successfully for standard_user.

Catalog - Medium / P2: All six inventory items display the same incorrect photograph, despite loading successfully.

Verification approach

The cart finding was checked against the product rows as well as the badge. The image finding was checked after loading and reload. The checkout finding was reproduced with two input methods, then compared with the same data on the working account.

Supporting material

A technical case study, ten website test cases, three defect reports, an importable Postman collection and the supporting execution records. The technical report connects each finding to a case and its evidence.

Project context: public demonstration services. SauceDemo intentionally exposes defects through problem_user. The two applications were tested separately. Method: browser-assisted functional checks and a Newman collection run. Priorities are proposed for this case study.
